Convergence

Nonlinear Equations

- Given function f , we seek value x for which
- $$f(x) = 0$$
- Solution x is **root** of equation, or **zero** of function f
 - So problem is known as **root finding** or **zero finding**

Michael T. Heath

Nonlinear Equations
Numerical Methods in One Dimension
Methods for Systems of Nonlinear Equations

Nonlinear Equations
Solutions and Sensitivity
Convergence

Examples: Nonlinear Equations

- Example of nonlinear equation in one dimension
- $$x^2 - 4 \sin(x) = 0$$
- for which $x = 1.9$ is one approximate solution
- Example of system of nonlinear equations in two dimensions

$$\begin{aligned} x_1^2 - x_2 + 0.25 &= 0 \\ -x_1 + x_2^2 + 0.25 &= 0 \end{aligned}$$

for which $x = [0.5 \ 0.5]^T$ is solution vector

Nonlinear Equations
Numerical Methods in One Dimension
Methods for Systems of Nonlinear Equations

Nonlinear Equations
Solutions and Sensitivity
Convergence

Examples: One Dimension

Nonlinear equations can have any number of solutions

- $\exp(x) + 1 = 0$ has no solution
- $\exp(-x) - x = 0$ has one solution
- $x^2 - 4 \sin(x) = 0$ has two solutions
- $x^3 + 6x^2 + 11x - 6 = 0$ has three solutions
- $\sin(x) = 0$ has infinitely many solutions

Nonlinear Equations
Numerical Methods in One Dimension
Methods for Systems of Nonlinear Equations

Nonlinear Equations
Solutions and Sensitivity
Convergence

Nonlinear Equations

Two important cases

- Single nonlinear equation in one unknown, where

$$f: \mathbb{R} \rightarrow \mathbb{R}$$

Solution is scalar x for which $f(x) = 0$

- System of n **coupled** nonlinear equations in n unknowns, where

$$f: \mathbb{R}^n \rightarrow \mathbb{R}^n$$

Solution is vector x for which all components of f are zero
simultaneously, $f(x) = 0$

Michael T. Heath

Scientific Computing

4 / 55

Nonlinear Equations
Numerical Methods in One Dimension
Methods for Systems of Nonlinear Equations

Nonlinear Equations
Solutions and Sensitivity
Convergence

Existence and Uniqueness

- Existence and uniqueness of solutions are more complicated for nonlinear equations than for linear equations
- For function $f: \mathbb{R} \rightarrow \mathbb{R}$, **bracket** is interval $[a, b]$ for which sign of f differs at endpoints
- If f is continuous and $\text{sign}(f(a)) \neq \text{sign}(f(b))$, then Intermediate Value Theorem implies there is $x^* \in [a, b]$ such that $f(x^*) = 0$
- There is no simple analog for n dimensions

Convergence

Example: Systems in Two Dimensions

$$\begin{aligned} x_1^2 - x_2 + \gamma &= 0 \\ -x_1 + x_2^2 + \gamma &= 0 \end{aligned}$$

Michael T. Heath

Scientific Computing

8 / 55

Multiplicity

- If $f(x^*) = f'(x^*) = f''(x^*) = \dots = f^{(m-1)}(x^*) = 0$ but $f^{(m)}(x^*) \neq 0$ (i.e., m th derivative is lowest derivative of f that does not vanish at x^*), then root x^* has **multiplicity** m

- If $m = 1$ ($f(x^*) = 0$ and $f'(x^*) \neq 0$), then x^* is **simple** root

Michael T. Heath

Scientific Computing

9 / 55

Sensitivity and Conditioning

Michael T. Heath

Scientific Computing

11 / 55

Convergence Rate

- For general iterative methods, define error at iteration k by

$$e_k = x_k - x^*$$

where x_k is approximate solution and x^* is true solution

- For methods that maintain interval known to contain solution, rather than specific approximate value for solution, take error to be length of interval containing solution

- Sequence converges with rate r if

$$\lim_{k \rightarrow \infty} \frac{\|e_{k+1}\|}{\|e_k\|^r} = C$$

for some finite nonzero constant C

Michael T. Heath

Scientific Computing

13 / 55

Interval Bisection Method

Bisection method begins with initial bracket and repeatedly halves its length until solution has been isolated as accurately as desired

```

while ((b - a) > tol) do
    m = a + (b - a)/2
    if sign(f(a)) = sign(f(m)) then
        a = m
    else
        b = m
    end
end
    
```

< interactive example >

Michael T. Heath

Scientific Computing

15 / 55

Sensitivity and Conditioning

- Conditioning of root finding problem is opposite to that for evaluating function
- Absolute condition number of root finding problem for root x^* of $f: \mathbb{R} \rightarrow \mathbb{R}$ is $1/|f'(x^*)|$
- Root is ill-conditioned if tangent line is nearly horizontal
- In particular, multiple root ($m > 1$) is ill-conditioned
- Absolute condition number of root finding problem for root x^* of $f: \mathbb{R}^n \rightarrow \mathbb{R}^n$ is $\|J_f^{-1}(x^*)\|$, where J_f is *Jacobian* matrix of f ,

$$\{J_f(x)\}_{ij} = \partial f_i(x) / \partial x_j$$

- Root is ill-conditioned if Jacobian matrix is nearly singular

Michael T. Heath

Scientific Computing

10 / 55

Sensitivity and Conditioning

- What do we mean by approximate solution \hat{x} to nonlinear system,

$$\|f(\hat{x})\| \approx 0 \quad \text{or} \quad \|\hat{x} - x^*\| \approx 0 ?$$

- First corresponds to "small residual," second measures closeness to (usually unknown) true solution x^*
- Solution criteria are not necessarily "small" simultaneously
- Small residual implies accurate solution only if problem is well-conditioned

Michael T. Heath

Scientific Computing

12 / 55

Convergence Rate, continued

Some particular cases of interest

- $r = 1$: **linear** ($C < 1$)
- $r > 1$: **superlinear**
- $r = 2$: **quadratic**

| Convergence rate | Digits gained per iteration |
|------------------|-----------------------------|
| linear | constant |
| superlinear | increasing |
| quadratic | double |

Michael T. Heath

Scientific Computing

14 / 55

Example: Bisection Method

$$f(x) = x^2 - 4 \sin(x) = 0$$

| a | $f(a)$ | b | $f(b)$ |
|----------|-----------|----------|----------|
| 1.000000 | -2.365884 | 3.000000 | 8.435520 |
| 1.000000 | -2.365884 | 2.000000 | 0.362810 |
| 1.500000 | -1.739980 | 2.000000 | 0.362810 |
| 1.750000 | -0.873444 | 2.000000 | 0.362810 |
| 1.875000 | -0.300718 | 2.000000 | 0.362810 |
| 1.875000 | -0.300718 | 1.937500 | 0.019849 |
| 1.906250 | -0.143255 | 1.937500 | 0.019849 |
| 1.921875 | -0.062406 | 1.937500 | 0.019849 |
| 1.929688 | -0.021454 | 1.937500 | 0.019849 |
| 1.933594 | -0.000846 | 1.937500 | 0.019849 |
| 1.933594 | -0.000846 | 1.935547 | 0.009491 |
| 1.933594 | -0.000846 | 1.934570 | 0.004320 |
| 1.933594 | -0.000846 | 1.934082 | 0.001736 |

Michael T. Heath

Scientific Computing

16 / 55

Bisection Method, continued

- Bisection method makes no use of magnitudes of function values, only their signs
- Bisection is certain to converge, but does so slowly
- At each iteration, length of interval containing solution reduced by half, convergence rate is **linear**, with $r = 1$ and $C = 0.5$
- One bit of accuracy is gained in approximate solution for each iteration of bisection
- Given starting interval $[a, b]$, length of interval after k iterations is $(b - a)/2^k$, so achieving error tolerance of tol requires

$$\left\lceil \log_2 \left(\frac{b - a}{tol} \right) \right\rceil$$

iterations, regardless of function f involved

Michael T. Heath

Scientific Computing

17 / 55

Example: Fixed-Point Problems

If $f(x) = x^2 - x - 2$, then fixed points of each of functions

- $g(x) = x^2 - 2$
- $g(x) = \sqrt{x + 2}$
- $g(x) = 1 + 2/x$
- $g(x) = \frac{x^2 + 2}{2x - 1}$

are solutions to equation $f(x) = 0$

Michael T. Heath

Scientific Computing

19 / 55

Example: Fixed-Point Iteration

Michael T. Heath

Scientific Computing

21 / 55

Convergence of Fixed-Point Iteration

- If $x^* = g(x^*)$ and $|g'(x^*)| < 1$, then there is interval containing x^* such that iteration
- $$x_{k+1} = g(x_k)$$
- converges to x^* if started within that interval
- If $|g'(x^*)| > 1$, then iterative scheme diverges
 - Asymptotic convergence rate of fixed-point iteration is usually linear, with constant $C = |g'(x^*)|$
 - But if $g'(x^*) = 0$, then convergence rate is at least quadratic

< interactive example >

Michael T. Heath

Scientific Computing

23 / 55

Fixed-Point Problems

- **Fixed point** of given function $g: \mathbb{R} \rightarrow \mathbb{R}$ is value x such that

$$x = g(x)$$

- Many iterative methods for solving nonlinear equations use **fixed-point iteration** scheme of form

$$x_{k+1} = g(x_k)$$

where fixed points for g are solutions for $f(x) = 0$

- Also called **functional iteration**, since function g is applied repeatedly to initial starting value x_0
- For given equation $f(x) = 0$, there may be many equivalent fixed-point problems $x = g(x)$ with different choices for g

Michael T. Heath

Scientific Computing

18 / 55

Example: Fixed-Point Problems

Michael T. Heath

Scientific Computing

20 / 55

Example: Fixed-Point Iteration

Michael T. Heath

Scientific Computing

22 / 55

Newton's Method

- Truncated Taylor series

$$f(x + h) \approx f(x) + f'(x)h$$

is linear function of h approximating f near x

- Replace nonlinear function f by this linear function, whose zero is $h = -f(x)/f'(x)$
- Zeros of original function and linear approximation are not identical, so repeat process, giving **Newton's method**

$$x_{k+1} = x_k - \frac{f(x_k)}{f'(x_k)}$$

Michael T. Heath

Scientific Computing

24 / 55

Newton's Method, continued

Newton's method approximates nonlinear function f near x_k by **tangent line** at $f(x_k)$

i

Michael T. Heath Scientific Computing 25 / 55

Convergence of Newton's Method

- Newton's method transforms nonlinear equation $f(x) = 0$ into fixed-point problem $x = g(x)$, where

$$g(x) = x - f(x)/f'(x)$$

and hence

$$g'(x) = f(x)f''(x)/(f'(x))^2$$

- If x^* is simple root (i.e., $f(x^*) = 0$ and $f'(x^*) \neq 0$), then $g'(x^*) = 0$
- Convergence rate of Newton's method for simple root is therefore **quadratic** ($r = 2$)
- But iterations must start close enough to root to converge

< interactive example >

i

Michael T. Heath Scientific Computing 27 / 55

Secant Method

- For each iteration, Newton's method requires evaluation of both function and its derivative, which may be inconvenient or expensive
- In **secant method**, derivative is approximated by finite difference using two successive iterates, so iteration becomes

$$x_{k+1} = x_k - f(x_k) \frac{x_k - x_{k-1}}{f(x_k) - f(x_{k-1})}$$

- Convergence rate of secant method is normally **superlinear**, with $r \approx 1.618$

i

Michael T. Heath Scientific Computing 29 / 55

Example: Secant Method

- Use secant method to find root of
- $$f(x) = x^2 - 4 \sin(x) = 0$$
- Taking $x_0 = 1$ and $x_1 = 3$ as starting guesses, we obtain

| x | $f(x)$ | h |
|----------|-----------|-----------|
| 1.000000 | -2.365884 | |
| 3.000000 | 8.435520 | -1.561930 |
| 1.438070 | -1.896774 | 0.286735 |
| 1.724805 | -0.977706 | 0.305029 |
| 2.029833 | 0.534305 | -0.107789 |
| 1.922044 | -0.061523 | 0.011130 |
| 1.933174 | -0.003064 | 0.000583 |
| 1.933757 | 0.000019 | -0.000004 |
| 1.933754 | 0.000000 | 0.000000 |

i

Michael T. Heath Scientific Computing 31 / 55

Example: Newton's Method

- Use Newton's method to find root of

$$f(x) = x^2 - 4 \sin(x) = 0$$

- Derivative is

$$f'(x) = 2x - 4 \cos(x)$$

so iteration scheme is

$$x_{k+1} = x_k - \frac{x_k^2 - 4 \sin(x_k)}{2x_k - 4 \cos(x_k)}$$

- Taking $x_0 = 3$ as starting value, we obtain

| x | $f(x)$ | $f'(x)$ | h |
|----------|----------|----------|-----------|
| 3.000000 | 8.435520 | 9.959970 | -0.846942 |
| 2.153058 | 1.294772 | 6.505771 | -0.199019 |
| 1.954039 | 0.108438 | 5.403795 | -0.020067 |
| 1.933972 | 0.001152 | 5.288919 | -0.000218 |
| 1.933754 | 0.000000 | 5.287670 | 0.000000 |

i

Michael T. Heath Scientific Computing 26 / 55

Newton's Method, continued

For multiple root, convergence rate of Newton's method is only linear, with constant $C = 1 - (1/m)$, where m is multiplicity

| k | $f(x) = x^2 - 1$ | $f(x) = x^2 - 2x + 1$ |
|-----|------------------|-----------------------|
| 0 | 2.0 | 2.0 |
| 1 | 1.25 | 1.5 |
| 2 | 1.025 | 1.25 |
| 3 | 1.0003 | 1.125 |
| 4 | 1.0000005 | 1.0625 |
| 5 | 1.0 | 1.03125 |

i

Michael T. Heath Scientific Computing 28 / 55

Secant Method, continued

Secant method approximates nonlinear function f by secant line through previous two iterates

< interactive example >

i

Michael T. Heath Scientific Computing 30 / 55

Higher-Degree Interpolation

- Secant method uses linear interpolation to approximate function whose zero is sought
- Higher convergence rate can be obtained by using higher-degree polynomial interpolation
- For example, quadratic interpolation (Muller's method) has superlinear convergence rate with $r \approx 1.839$
- Unfortunately, using higher degree polynomial also has disadvantages
 - interpolating polynomial may not have real roots
 - roots may not be easy to compute
 - choice of root to use as next iterate may not be obvious

i

Michael T. Heath Scientific Computing 32 / 55

Inverse Interpolation

- Good alternative is **inverse interpolation**, where x_k are interpolated as function of $y_k = f(x_k)$ by polynomial $p(y)$, so next approximate solution is $p(0)$
- Most commonly used for root finding is inverse quadratic interpolation

Michael T. Heath Scientific Computing 33 / 55

Example: Inverse Quadratic Interpolation

- Use inverse quadratic interpolation to find root of

$$f(x) = x^2 - 4 \sin(x) = 0$$

- Taking $x = 1, 2$, and 3 as starting values, we obtain

| x | $f(x)$ | h |
|----------|-----------|-----------|
| 1.000000 | -2.365884 | |
| 2.000000 | 0.362810 | |
| 3.000000 | 8.435520 | |
| 1.886318 | -0.244343 | -0.113682 |
| 1.939558 | 0.030786 | 0.053240 |
| 1.933742 | -0.000060 | -0.005815 |
| 1.933754 | 0.000000 | 0.000011 |
| 1.933754 | 0.000000 | 0.000000 |

Michael T. Heath Scientific Computing 35 / 55

Example: Linear Fractional Interpolation

- Use linear fractional interpolation to find root of

$$f(x) = x^2 - 4 \sin(x) = 0$$

- Taking $x = 1, 2$, and 3 as starting values, we obtain

| x | $f(x)$ | h |
|----------|-----------|-----------|
| 1.000000 | -2.365884 | |
| 2.000000 | 0.362810 | |
| 3.000000 | 8.435520 | |
| 1.906953 | -0.139647 | -1.093047 |
| 1.933351 | -0.002131 | 0.026398 |
| 1.933756 | 0.000013 | -0.000406 |
| 1.933754 | 0.000000 | -0.000003 |

< interactive example >

Michael T. Heath Scientific Computing 37 / 55

Safeguarded Methods, continued

- Fast method can then be tried again on smaller interval with greater chance of success
- Ultimately, convergence rate of fast method should prevail
- Hybrid approach seldom does worse than safe method, and usually does much better
- Popular combination is bisection and inverse quadratic interpolation, for which no derivatives required

Michael T. Heath Scientific Computing 39 / 55

Inverse Quadratic Interpolation

- Given approximate solution values a, b, c , with function values f_a, f_b, f_c , next approximate solution found by fitting quadratic polynomial to a, b, c as function of f_a, f_b, f_c , then evaluating polynomial at 0
- Based on nontrivial derivation using Lagrange interpolation, we compute

$$u = f_b/f_c, \quad v = f_b/f_a, \quad w = f_a/f_c$$

$$p = v(w(u - w)(c - b) - (1 - u)(b - a))$$

$$q = (w - 1)(u - 1)(v - 1)$$

then new approximate solution is $b + p/q$

- Convergence rate is normally $r \approx 1.839$

< interactive example >

Michael T. Heath Scientific Computing 34 / 55

Linear Fractional Interpolation

- Interpolation using rational fraction of form

$$\phi(x) = \frac{x - u}{vx - w}$$

is especially useful for finding zeros of functions having horizontal or vertical asymptotes

- ϕ has zero at $x = u$, vertical asymptote at $x = w/v$, and horizontal asymptote at $y = 1/v$
- Given approximate solution values a, b, c , with function values f_a, f_b, f_c , next approximate solution is $c + h$, where

$$h = \frac{(a - c)(b - c)(f_a - f_b)f_c}{(a - c)(f_c - f_b)f_a - (b - c)(f_c - f_a)f_b}$$

- Convergence rate is normally $r \approx 1.839$, same as for quadratic interpolation (inverse or regular)

Michael T. Heath Scientific Computing 36 / 55

Safeguarded Methods

- Rapidly convergent methods for solving nonlinear equations may not converge unless started close to solution, but safe methods are slow
- Hybrid methods combine features of both types of methods to achieve both speed and reliability
- Use rapidly convergent method, but maintain bracket around solution
- If next approximate solution given by fast method falls outside bracketing interval, perform one iteration of safe method, such as bisection

Michael T. Heath Scientific Computing 38 / 55

Zeros of Polynomials

- For polynomial $p(x)$ of degree n , one may want to find all n of its zeros, which may be complex even if coefficients are real
- Several approaches are available
 - Use root-finding method such as Newton's or Muller's method to find one root, deflate it out, and repeat
 - Form companion matrix of polynomial and use eigenvalue routine to compute all its eigenvalues
 - Use method designed specifically for finding all roots of polynomial, such as Jenkins-Traub

Michael T. Heath Scientific Computing 40 / 55

Solving systems of nonlinear equations is much more difficult than scalar case because

- Wider variety of behavior is possible, so determining existence and number of solutions or good starting guess is much more complex
- There is no simple way, in general, to guarantee convergence to desired solution or to bracket solution to produce absolutely safe method
- Computational overhead increases rapidly with dimension of problem

- In n dimensions, **Newton's method** has form

$$\mathbf{x}_{k+1} = \mathbf{x}_k - \mathbf{J}(\mathbf{x}_k)^{-1} \mathbf{f}(\mathbf{x}_k)$$

where $\mathbf{J}(\mathbf{x})$ is Jacobian matrix of \mathbf{f} ,

$$\{\mathbf{J}(\mathbf{x})\}_{ij} = \frac{\partial f_i(\mathbf{x})}{\partial x_j}$$

- In practice, we do not explicitly invert $\mathbf{J}(\mathbf{x}_k)$, but instead solve linear system

$$\mathbf{J}(\mathbf{x}_k) \mathbf{s}_k = -\mathbf{f}(\mathbf{x}_k)$$

for **Newton step** \mathbf{s}_k , then take as next iterate

$$\mathbf{x}_{k+1} = \mathbf{x}_k + \mathbf{s}_k$$

- Evaluating at new point,

$$\mathbf{f}(\mathbf{x}_1) = \begin{bmatrix} 0 \\ 4.72 \end{bmatrix}, \quad \mathbf{J}_f(\mathbf{x}_1) = \begin{bmatrix} 1 & 2 \\ -1.67 & 11.3 \end{bmatrix}$$

- Solving system $\begin{bmatrix} 1 & 2 \\ -1.67 & 11.3 \end{bmatrix} \mathbf{s}_1 = \begin{bmatrix} 0 \\ -4.72 \end{bmatrix}$ gives $\mathbf{s}_1 = [0.64 \quad -0.32]^T$, so $\mathbf{x}_2 = \mathbf{x}_1 + \mathbf{s}_1 = [-0.19 \quad 1.10]^T$

- Evaluating at new point,

$$\mathbf{f}(\mathbf{x}_2) = \begin{bmatrix} 0 \\ 0.83 \end{bmatrix}, \quad \mathbf{J}_f(\mathbf{x}_2) = \begin{bmatrix} 1 & 2 \\ -0.38 & 8.76 \end{bmatrix}$$

- Iterations eventually convergence to solution $\mathbf{x}^* = [0 \quad 1]^T$

< interactive example >

Cost per iteration of Newton's method for dense problem in n dimensions is substantial

- Computing Jacobian matrix costs n^2 scalar function evaluations
- Solving linear system costs $\mathcal{O}(n^3)$ operations

- **Fixed-point problem** for $g: \mathbb{R}^n \rightarrow \mathbb{R}^n$ is to find vector \mathbf{x} such that

$$\mathbf{x} = g(\mathbf{x})$$

- Corresponding **fixed-point iteration** is

$$\mathbf{x}_{k+1} = g(\mathbf{x}_k)$$

- If $\rho(\mathbf{G}(\mathbf{x}^*)) < 1$, where ρ is **spectral radius** and $\mathbf{G}(\mathbf{x})$ is Jacobian matrix of g evaluated at \mathbf{x} , then fixed-point iteration converges if started close enough to solution
- Convergence rate is normally linear, with constant C given by spectral radius $\rho(\mathbf{G}(\mathbf{x}^*))$
- If $\mathbf{G}(\mathbf{x}^*) = \mathbf{O}$, then convergence rate is at least quadratic

- Use Newton's method to solve nonlinear system

$$\mathbf{f}(\mathbf{x}) = \begin{bmatrix} x_1 + 2x_2 - 2 \\ x_1^2 + 4x_2^2 - 4 \end{bmatrix} = \mathbf{0}$$

- Jacobian matrix is $\mathbf{J}_f(\mathbf{x}) = \begin{bmatrix} 1 & 2 \\ 2x_1 & 8x_2 \end{bmatrix}$

- If we take $\mathbf{x}_0 = [1 \quad 2]^T$, then

$$\mathbf{f}(\mathbf{x}_0) = \begin{bmatrix} 3 \\ 13 \end{bmatrix}, \quad \mathbf{J}_f(\mathbf{x}_0) = \begin{bmatrix} 1 & 2 \\ 2 & 16 \end{bmatrix}$$

- Solving system $\begin{bmatrix} 1 & 2 \\ 2 & 16 \end{bmatrix} \mathbf{s}_0 = \begin{bmatrix} -3 \\ -13 \end{bmatrix}$ gives $\mathbf{s}_0 = \begin{bmatrix} -1.83 \\ -0.58 \end{bmatrix}$,
so $\mathbf{x}_1 = \mathbf{x}_0 + \mathbf{s}_0 = [-0.83 \quad 1.42]^T$

- Differentiating corresponding fixed-point operator

$$g(\mathbf{x}) = \mathbf{x} - \mathbf{J}(\mathbf{x})^{-1} \mathbf{f}(\mathbf{x})$$

and evaluating at solution \mathbf{x}^* gives

$$\mathbf{G}(\mathbf{x}^*) = \mathbf{I} - (\mathbf{J}(\mathbf{x}^*)^{-1} \mathbf{J}(\mathbf{x}^*) + \sum_{i=1}^n f_i(\mathbf{x}^*) \mathbf{H}_i(\mathbf{x}^*)) = \mathbf{O}$$

where $\mathbf{H}_i(\mathbf{x})$ is component matrix of derivative of $\mathbf{J}(\mathbf{x})^{-1}$

- Convergence rate of Newton's method for nonlinear systems is normally **quadratic**, provided Jacobian matrix $\mathbf{J}(\mathbf{x}^*)$ is nonsingular
- But it must be started close enough to solution to converge

- **Secant updating** methods reduce cost by

- Using function values at successive iterates to build approximate Jacobian and avoiding explicit evaluation of derivatives
- Updating factorization of approximate Jacobian rather than refactoring it each iteration
- Most secant updating methods have superlinear but not quadratic convergence rate
- Secant updating methods often cost less overall than Newton's method because of lower cost per iteration

Broyden's Method

- *Broyden's method* is typical secant updating method
- Beginning with initial guess x_0 for solution and initial approximate Jacobian B_0 , following steps are repeated until convergence

x_0 = initial guess

B_0 = initial Jacobian approximation

for $k = 0, 1, 2, \dots$

Solve $B_k s_k = -f(x_k)$ for s_k

$x_{k+1} = x_k + s_k$

$y_k = f(x_{k+1}) - f(x_k)$

$B_{k+1} = B_k + ((y_k - B_k s_k) s_k^T) / (s_k^T s_k)$

end

Example: Broyden's Method

- Use Broyden's method to solve nonlinear system

$$f(x) = \begin{bmatrix} x_1 + 2x_2 - 2 \\ x_1^2 + 4x_2^2 - 4 \end{bmatrix} = 0$$

- If $x_0 = [1 \ 2]^T$, then $f(x_0) = [3 \ 13]^T$, and we choose

$$B_0 = J_f(x_0) = \begin{bmatrix} 1 & 2 \\ 2 & 16 \end{bmatrix}$$

- Solving system

$$\begin{bmatrix} 1 & 2 \\ 2 & 16 \end{bmatrix} s_0 = \begin{bmatrix} -3 \\ -13 \end{bmatrix}$$

$$\text{gives } s_0 = \begin{bmatrix} -1.83 \\ -0.58 \end{bmatrix}, \text{ so } x_1 = x_0 + s_0 = \begin{bmatrix} -0.83 \\ 1.42 \end{bmatrix}$$

Michael T. Heath

Scientific Computing

51 / 55

Example, continued

- Evaluating at new point x_2 gives $f(x_2) = \begin{bmatrix} 0 \\ 1.08 \end{bmatrix}$, so

$$y_1 = f(x_2) - f(x_1) = \begin{bmatrix} 0 \\ -3.64 \end{bmatrix}$$

- From updating formula, we obtain

$$B_2 = \begin{bmatrix} 1 & 2 \\ -0.34 & 15.3 \end{bmatrix} + \begin{bmatrix} 0 & 0 \\ 1.46 & -0.73 \end{bmatrix} = \begin{bmatrix} 1 & 2 \\ 1.12 & 14.5 \end{bmatrix}$$

- Iterations continue until convergence to solution $x^* = \begin{bmatrix} 0 \\ 1 \end{bmatrix}$

Trust-Region Methods

- Another approach is to maintain estimate of *trust region* where Taylor series approximation, upon which Newton's method is based, is sufficiently accurate for resulting computed step to be reliable
- Adjusting size of trust region to constrain step size when necessary usually enables progress toward solution even starting far away, yet still permits rapid converge once near solution
- Unlike damped Newton method, trust region method may modify direction as well as length of Newton step
- More details on this approach will be given in Chapter 6

Broyden's Method, continued

- Motivation for formula for B_{k+1} is to make least change to B_k subject to satisfying *secant equation*

$$B_{k+1}(x_{k+1} - x_k) = f(x_{k+1}) - f(x_k)$$

- In practice, factorization of B_k is updated instead of updating B_k directly, so total cost per iteration is only $\mathcal{O}(n^2)$

Example, continued

- Evaluating at new point x_1 gives $f(x_1) = \begin{bmatrix} 0 \\ 4.72 \end{bmatrix}$, so

$$y_0 = f(x_1) - f(x_0) = \begin{bmatrix} -3 \\ -8.28 \end{bmatrix}$$

- From updating formula, we obtain

$$B_1 = \begin{bmatrix} 1 & 2 \\ 2 & 16 \end{bmatrix} + \begin{bmatrix} 0 & 0 \\ -2.34 & -0.74 \end{bmatrix} = \begin{bmatrix} 1 & 2 \\ -0.34 & 15.3 \end{bmatrix}$$

- Solving system

$$\begin{bmatrix} 1 & 2 \\ -0.34 & 15.3 \end{bmatrix} s_1 = \begin{bmatrix} 0 \\ -4.72 \end{bmatrix}$$

$$\text{gives } s_1 = \begin{bmatrix} 0.59 \\ -0.30 \end{bmatrix}, \text{ so } x_2 = x_1 + s_1 = \begin{bmatrix} -0.24 \\ 1.120 \end{bmatrix}$$

Robust Newton-Like Methods

- Newton's method and its variants may fail to converge when started far from solution
- Safeguards can enlarge region of convergence of Newton-like methods
- Simplest precaution is *damped Newton method*, in which new iterate is

$$x_{k+1} = x_k + \alpha_k s_k$$
 where s_k is Newton (or Newton-like) step and α_k is scalar parameter chosen to ensure progress toward solution
- Parameter α_k reduces Newton step when it is too large, but $\alpha_k = 1$ suffices near solution and still yields fast asymptotic convergence rate
